## Assignment 2

Jonathan Guymont, Marzieh Mehdizadeh

### 1 Linear and non-linear regularized regression

#### 1.1 Linear Regression

(1) The set of parameters is  $\theta = \{w_1, \dots, w_d, b\}$  where  $w_i \in \mathbb{R}$  for  $i = 1, \dots, d$  and  $b \in \mathbb{R}$ . The  $w_i$  are the coefficients of the different features of the inputs random variable  $x_1, \dots, x_d$  and  $b$  is the bias.

(2)

$$\begin{aligned}\hat{R}((x, t), f) &= \sum_{i=1}^n (f(\mathbf{x}^{(i)}) - t^{(i)})^2 \\ &= \sum_{i=1}^n (b + \mathbf{w}^\top \mathbf{x}^{(i)} - t^{(i)})^2\end{aligned}\tag{1}$$

(3) We rewrite the loss with matrix instead. Let  $X \in \mathbb{R}^{n \times d+1}$  be the design matrix where the rows are the different training examples and the first column is a row of ones that we add for convenience. Also lets redefine the weight vector as  $\mathbf{w}^{top} = (b, w_1, \dots, w_d)$ . In this new formulation of the input and parameters, we have that  $\mathbf{w}^\top \mathbf{x} \equiv b + \mathbf{w}'^\top \mathbf{x}'$ , where  $"'$ " indicates the previous format. Let  $\hat{Y} \in \mathbb{R}^n$  be the vector of predictions for all the training examples and  $Y = (t^{(1)}, \dots, t^{(n)})^\top$ . We have  $\hat{Y} \in \mathbb{R}^n = X\mathbf{w}$ . It follows that  $\hat{R}((x, t), f) = (\hat{Y} - Y)^\top (\hat{Y} - Y) = (X\mathbf{w} - Y)^\top (X\mathbf{w} - Y)$

$$\begin{aligned}(X\mathbf{w} - Y)(X\mathbf{w} - Y)^\top &= (-Y^\top + \mathbf{w}^\top X^\top)(X\mathbf{w} - Y) \\ &= \mathbf{w}^\top X^\top X\mathbf{w} - Y^\top X\mathbf{w} - \mathbf{w}^\top X^\top Y + Y^\top Y \\ &= \mathbf{w}^\top X^\top X\mathbf{w} - 2\mathbf{w}^\top X^\top Y + Y^\top Y \quad (Y^\top X\mathbf{w} = \mathbf{w}^\top X^\top Y)\end{aligned}\tag{2}$$

where the last equality is true because  $Y^\top X\mathbf{w}$  and  $\mathbf{w}^\top X^\top Y$  are both the same scalar. And the derivative wrt  $w$  is given by

$$\frac{\partial}{\partial \mathbf{w}} \mathbf{w}^\top X^\top X\mathbf{w} - 2\mathbf{w}^\top X^\top Y + Y^\top Y = 2X^\top X\mathbf{w} - 2X^\top Y\tag{3}$$

Setting the derivatives to zero

$$\begin{aligned}2X^\top X\mathbf{w} - 2X^\top Y &= 0 \\ X^\top X\mathbf{w} &= X^\top Y \\ \mathbf{w}^* &= (X^\top X)^{-1} X^\top Y\end{aligned}\tag{4}$$

(4) While  $\|w\| > \epsilon$  Do:

$$\mathbf{w}_t = \mathbf{w}_{t-1} - \lambda \cdot 2(X^\top X \mathbf{w}_{t-1} - X^\top Y)$$

where  $\epsilon$  is some level of tolerance beyond which we are satisfied with the solution (gradient is flat enough).

(5) The gradient can be rewritten as  $2 \cdot (X^\top \hat{Y} - X^\top Y) = 2X^\top \cdot (\hat{Y} - Y) = 2X^\top \boldsymbol{\epsilon}$ , where  $\boldsymbol{\epsilon}$  is the vector of errors (one for each examples). For a single point, the gradient is equal to  $2\mathbf{x}^{(i)}\epsilon^{(i)}$ . We can see that the higher the error, the bigger the step. Also we always move in either the direction of  $\mathbf{x}$  or in the opposite direction, and proportionally to the magnitude of the error.

## 1.2 Ridge Regression

(1) The gradient of the regularized risk is equal to the gradient of the unregularized risk plus the gradient of the regularizer.

$$\frac{\partial}{\partial \mathbf{w}} \hat{R} = 2(X^\top X \mathbf{w}_{t-1} - X^\top Y) + 2\lambda \mathbf{w}$$

(2) While  $\|w\| > \epsilon$  Do:

$$\mathbf{w}_t \leftarrow \mathbf{w}_{t-1} - \eta \cdot 2(X^\top X \mathbf{w}_{t-1} - X^\top Y + \lambda \mathbf{w}_{t-1})$$

where  $\epsilon$  is some level of tolerance beyond which we are satisfied with the solution (the gradient is flat enough).

(3) The gradient in (1) is already written in term of matrices. The regularized risk is given by

$$\hat{R} = (X\mathbf{w} - Y)(X\mathbf{w} - Y)^\top + \lambda \|\mathbf{w}\|^2$$

(4) Setting the derivative in (1) to zero

$$\begin{aligned} 2(X^\top X \mathbf{w} - X^\top Y) + 2\lambda \mathbf{w} &= 0 \\ X^\top X \mathbf{w} + \lambda \mathbf{w} &= X^\top Y \\ (X^\top X + \lambda I) \mathbf{w} &= X^\top Y \\ \mathbf{w}^* &= (X^\top X + \lambda I)^{-1} X^\top Y \end{aligned} \tag{5}$$

If  $\lambda = 0$  whatever  $N$  is, the empirical risk will equal to the unregularized one. The number of examples  $N$  do not affect the shape of the gradient (the gradient is always in  $\mathbb{R}^d$  whatever  $N$  is).

## 1.3 Regression with a fixed non-linear pre-processing

(1)  $\tilde{f}_k(x) = b + \sum_{i=1}^k w_i x^i = b + \mathbf{w}^\top \phi_k(x)$

(2)  $b$  is a scalar and  $w_1, \dots, w_k$  are also scalars and the coefficient of the polynomial terms.

(3)  $\phi_1(x) = x$  so this one is a linear regression.

$$\tilde{f}_1(\boldsymbol{x}) = b + w_1x_1 + w_2x_2$$

$$\tilde{f}_2(\boldsymbol{x}) = b + w_1x_1 + w_2x_2 + w_3x_1^2 + w_4x_2^2 + w_5x_1x_2$$

$$\tilde{f}_3(\boldsymbol{x}) = b + w_1x_1 + w_2x_2 + w_3x_1^2 + w_4x_2^2 + w_5x_1x_2 + w_6x_1^2x_2 + w_7x_1x_2^2 + w_8x_1^3 + w_9x_2^3$$
